Port mirroring (SPAN): This technique involves configuring a switch to copy network traffic from one or more ports to a monitoring port. The monitoring port is then connected to a packet capture device, such as a laptop or a dedicated server, to capture and analyze. A network switch is a device that connects other devices together in a computer network. Here we are specifically discussing computer networks, but of course there are switches in other fields too. All operate in similar ways, by connecting different devices through their physical ports. A Cisco router is used as an example, but the procedure applies to any SNMP-enabled network device. The Cisco method is called Switched Port Analyser also known as SPAN. This is usually the point to. Network monitoring is the process of continuously monitoring a network for any reason like any system failure, slow traffic, some network-related problem, some data analytics etc. It is a very important process that helps to discover, map and monitor the network and the related devices and network. From the backbone routers that facilitate data flow to the intricate web of switches managing local connections, maintaining a vigilant eye on your network devices is at the core of ensuring a high functioning network infrastructure.

Metered PDUs monitor load levels to avoid potential overloads via a LCD display. Monitored PDUs remotely monitor voltage, frequency, and load levels via a built-in network connection. Switched
