PDU is an electrical panel that takes high-capacity input power from a UPS or switchgear and distributes power in a controlled way with individual circuit breakers that feed Individual racks/cabinets. In a typical mission critical facility, these will be placed in data hall. Electrical systems define whether a data center can operate safely, continuously, and efficiently under real-world load conditions. As AI workloads, higher rack densities, and stricter energy regulations increase demand on power infrastructure, design teams need more than standard capacity. Designing an efficient electrical distribution system and power supply for a data center isn't just about delivering electricity--it's about achieving high reliability, handling high power densities, minimising power outages, and optimising for energy performance (e., low power usage effectiveness. Here's how electricity is delivered to data centers: 1. Power Transmission Data centers get power from utility companies transmitting from generation plants such as hydroelectric, nuclear, or renewable sources over high-voltage transmission lines.

We can say that the power distribution system is the heart of any critical facility, and it's vital that everyone working in and around critical sites
